

While initial diode laser research was conducted on simple P-N diodes, all modern lasers use the double-hetero-structure implementation, where the carriers and the photons are confined in order to ...

In principle, a laser diode that directly generates green light and is made entirely using well-understood semiconductor fabrication techniques would be preferable.

Direct green laser diodes are an important step toward powerful embedded projectors. The laborious way of producing green light by doubling the frequency of infrared laser is no longer needed.

Unlike formal red or infrared lasers, green diode laser gets even more visible laser light emission, and less light spread. It enables even longer distance laser light projecting under use of ...

It uses an infrared laser diode to pump light into a crystal or glass that is doped with ions, usually neodymium. This pumped light energizes the ions, causing them to emit photons. These ...

To operate, laser diodes must induce photon emission at a semiconductor junction. Emissions from a laser diode can be classified into three categories based on how they are ...

In 1996, this system enabled the first laser diode on the short wavelength side of the visible spectrum--405 nm, the "sweet spot" for light emitters based on InGaN quantum wells (QWs). Since ...

The green diodes are based on the GaN technology developed in the 1990s for blue laser diodes. Adding indium reduces the bandgap of GaN and shifts its emission to longer wavelengths, but adding ...

The light in LEDs and laser diodes is produced in a similar way, and the colors are similar; however, the properties are completely different. The main difference between these ...

In this paper, we describe a method for realizing twice-combined polarized beams by selectively changing the polarization state of lasers with different wavelengths. This improves the ...
